Improvement of the Performance of Database Access Operations in Cellular Networks

Mustafa Vahabzadeh Dolama and Akbar Ghaffarpour Rahbar

Computer Networks Research Lab, Department of Electrical Engineering, Sahand University of Technology, Tabriz, Iran

Abstract—Reducing the traffic volume of location updating is a critical issue for tracking mobile users in a cellular network. Besides, when user \( x \) wants to communicate with user \( y \), the location of user \( y \) must be extracted from databases. Therefore, one or more databases must be accessed for updating, recording, deleting, and searching. Thus, the most important criterion of a location tracking algorithm is to provide a small database access time. In this paper, we propose a new location tracking scheme, called Virtual Overlap Region with Forwarding Pointer (VF), and compare the number of database accesses required for updating, deleting, and searching operations for the proposed scheme and other approaches proposed for cellular networks. Our VF scheme like Overlap Region scheme reduces the updating information when a user frequently moves in boundaries of LAs. Unlike Overlap Region, the VF can reduce number of database accesses for searching users’ information.

Keywords—Cellular networks, deleting cost, GSM, searching cost, tracking mobile users, UMTS, updating cost.

1. Introduction

In mobile communications (e.g., GSM, UMTS, 3G,...), the location of users is not fixed and may change in time. Therefore, to make a communication between user \( x \) and user \( y \), the system must first find the location of user \( y \). Therefore, the location of users must be tracked from time to time [1]. In mobile communications, a small geographical area (called cell) is served by a Base Station (BS). Several cells are grouped into a Location Area (LA) and several LAs make a mobile communications network. The Mobile Terminals (MTs) in a cell directly communicate with the BS of the cell. Several BSs are connected to a Base Station Controller (BSC) and several BSCs are connected to a Mobile Switching Center (MSC) [2], [3].

In a typical telephone system, we have one database that stores all users’ information permanently. Therefore, the location of each user can be found easily by searching the database. However, in cellular networks the location of users is not fixed. When a user enters a new location, the information of this user must be updated. With the increase of the number of mobile users in cellular networks, the database access time becomes a bottleneck because more database access operations (for updating, deleting, searching, and recording new information) are necessitated in time [4]. Thus, choosing a good algorithm for tracking users in cellular networks depends on the number of needed database accesses.

The objective of this paper is to propose a new method for tracking mobile users and compare the number of database accesses for the proposed method with other available methods. The proposed scheme uses the concept of virtual overlap region and forwarding pointer, but with a different policy for updating the information when a user frequently moves in boundaries of LAs in one overlap region. Indeed, the number of database accesses for searching users’ locations and updating their information can be reduced efficiently. To the best of our knowledge, this is the first time mobile tracking schemes have been compared based on their database access operations (updating, searching, deleting, etc.), except our recent work in [5].

Our contributions in this paper are proposal of the Virtual Overlap Region with Forwarding Pointer (VF) location tracking scheme, and comparison of location tracking schemes based on database access operations.

The remainder of this paper is organized as follows. Location management schemes are explained in Section 2. The proposed VF method is described in Section 3. In Section 4, we compare location management methods. Finally, a brief conclusion is presented in Section 5.

2. The Schemes Proposed for Tracking Mobile Users

Many strategies have been proposed to reduce the overhead of database accesses in mobile communications networks [6]–[13]. In this section, we will briefly describe and compare some location management approaches such as two-tier architecture [7], Forwarding Pointer [6], Virtual Layer [8], Virtual Layer with Forwarding Pointer [9], and Overlap Region [10].

2.1. Two-Tier Architecture

Two-tier architecture [7] uses a two-level database system: HLR that maintains all permanent information of each user and a pointer to another database; and Visitor Location Register (VLR) that stores temporary location information.
of users. The VLR database is maintained at each LA. Therefore,

- When mobile user \( x \) enters the mobile communications network (i.e., user turns the mobile on), a new record is created in both HLR and VLR in order to store the information of user \( x \). Thus, one HLR and one VLR access are required.

- When mobile user \( x \) moves from LA\(_i\) to LA\(_j\), the information of the user \( x \) in VLR\(_i\) is deleted and a new record is created in VLR\(_j\). In addition, a message is sent to HLR by VLR\(_j\) in order to update the user \( x \) pointer from VLR\(_i\) to VLR\(_j\). Therefore, one HLR access and two VLR accesses are necessary.

- When mobile user \( x \) decides to call mobile user \( y \):
  - if both user \( x \) and user \( y \) are in the same LA\(_i\), the location of user \( y \) is found from VLR\(_i\). Thus, one VLR access is needed;
  - if both user \( x \) and user \( y \) are not in the same LA\(_i\), first, the location of user \( y \) is searched in VLR\(_i\). Since the information cannot be found in VLR\(_i\), the relevant VLR\(_j\) can be found from HLR. Finally, the location of user \( y \) is found from VLR\(_j\). Therefore, one HLR access and two VLR accesses are required to find the location of user \( y \).

Since the access of the HLR database takes more time than the access of a VLR database due to the large size of the HLR database, the two-tier architecture can reduce the search cost when both user \( x \) and user \( y \) are in the same LA. However, when user \( x \) and user \( y \) are not in the same LA, the HLR, the new VLR, and old VLR all must be accessed for appropriate functions. This, in turn, increases the number of database accesses.

- Finally, when user \( x \) turns his/her mobile off or exits from the mobile communications network, the information of user \( x \) in HLR and VLR should be deleted. To delete the information of user \( x \), one HLR and one VLR accesses are necessitated.

### 2.2. Forwarding Pointer

When a user frequently moves in a boundary between LAs, more HLR accesses are required for updating in the two-tier architecture and HLR may likely become a bottleneck. The Forwarding Pointers scheme [6] has been proposed to efficiently reduce the volume of HLR accesses required for updating. In this approach, the main idea is to set up a forwarding pointer from an old database to a new database when a user leaves the old LA toward a new LA. Therefore,

- When mobile user \( x \) enters a mobile communications network (i.e., user \( x \) turns his/her mobile on), a new record is created in both HLR and VLR in order to store the information of user \( x \). Thus, one HLR and one VLR access are needed.

- When mobile user \( x \) moves from LA\(_i\) to LA\(_j\), a new record is created in VLR\(_j\) and a pointer is set to VLR\(_i\). Therefore, two VLR accesses are only needed.

- When mobile user \( x \) calls mobile user \( y \):
  - If both user \( x \) and user \( y \) are in the same LA\(_i\), the location of user \( y \) is either directly found from VLR\(_i\), or is following the pointers chain. Thus, one VLR access is necessitated where \( l \) is the length of the pointers chain. We have \( l = 1 \) if the information is retrieved directly from VLR\(_i\).
  - If both user \( x \) and user \( y \) are not in the same LA\(_i\), the location of user \( y \) is first searched in VLR\(_i\) and the relevant pointers chain. Since the information cannot be found, the relevant VLR\(_j\) can be found from HLR. Finally, the location of user \( y \) is either directly found from VLR\(_j\) or by following the pointers chain. Therefore, one HLR access and \( 2 \times l \) VLR accesses are needed to find the location of user \( y \).

- Finally, when user \( x \) turns his/her mobile off or exits from the mobile communications network, the information of user \( x \) in HLR and VLR must be deleted. One HLR and \( l \) VLR accesses are needed to delete the information of user \( x \).

Since no update is required in the HLR database, the update cost goes down. When the length of the pointer chain is less than five, according to analytical estimation in [6], this scheme can reduce the total cost by 20% to 60%. Although, this scheme can reduce the total cost, the frequent updates problem still exists when a user moves back and forward in the boundary of an LA.

### 2.3. Virtual Layer Scheme

The virtual layer scheme [8] has been proposed to construct a new location database architecture (see Fig. 1). The bold lines in Fig. 1 represent the original layer and the dotted lines represent the virtual layer. For every virtual layer, one VLR is needed (i.e., subVLR). In this scheme, one SubMSC is necessitated for each virtual layer. The SubMSCs are connected to the covered MSC. For example in Fig. 1, consider MT\(_i\) moves from position A to B, B to C and then comes back to position A. Initially in position A, HLR and VLR1 have created an entry for MT\(_i\). When MT\(_i\) moves to position B, the SubMSC4 creates a new entry for MT\(_i\) and VLR1 must be updated. Then, when MT\(_i\) moves from position B to C and C to A, no update is needed because the virtual layer has not changed. The goal of this scheme is to reduce both location updating rate and location updating cost, especially when the MTs
Fig. 1. The demonstration of the virtual layer.

reside near the boundaries of LA and frequently cross through the boundary to another LA.

- When mobile user \( x \) enters the mobile communications network (i.e., user \( x \) turns the mobile on), a new record is created in both HLR and VLR in order to store the information of user \( x \). Thus, one HLR and one VLR accesses are necessitated.

- When VLR is active: mobile user \( x \) moves from one LA, \( i \) to LA, \( j \):
  - If the information of user \( x \) already exists in subVLR, \( k \), VLR, \( i \), must be deactivated and subVLR, \( k \), must be activated. Therefore, one VLR and one subVLR accesses are necessary.
  - If the information of user \( x \) does not exist in subVLR, \( k \), a new record is created in subVLR, \( k \), and the information in previous subVLR must be deleted. Besides, VLR, \( i \), must be deactivated and subVLR, \( k \), must be activated. Therefore, one VLR and two subVLR accesses should be done.

- When subVLR is active: mobile user \( x \) moves from virtual layer, \( i \) to virtual layer, \( j \):
  - If the information exists in VLR, \( k \), the information in VLR, \( k \), is updated. VLR, \( k \), must be activated and subVLR must be deactivated. Therefore, one VLR and one subVLR accesses are required.
  - If the information does not exist in VLR, \( k \), a new record is created in VLR, \( k \), and the previous record must be deleted. Hence, a message is sent to HLR by VLR, \( k \), in order to update the user, \( x \), VLR pointer (from previous VLR to VLR, \( j \)). Besides, VLR, \( k \), must be activated and subVLR, \( k \), must be deactivated. Thus, one HLR access, one subVLR, and two VLR accesses are required.

- When mobile user \( x \) calls mobile user \( y \):
  - If both user \( x \) and user \( y \) are in the same LA, \( i \), the location of user \( y \) is found from VLR, \( i \). Thus, one VLR access is needed.
  - If both user \( x \) and user \( y \) are not in the same LA, \( i \), the location of user \( y \) is first searched in VLR, \( i \). Since the information cannot be found from VLR, \( i \), the relevant VLR, \( j \), can be found from HLR. Finally, the location of user \( y \) is found from VLR, \( j \). Therefore, one HLR access and two VLR accesses are necessitated to find the location of user \( y \).

- Finally, when user \( x \) turns his/her mobile off, or exits from the mobile communications network, the information of user \( x \) in HLR and VLR should be deleted. For this purpose, one HLR and one VLR accesses are necessary.

2.4. Virtual Layer with Forwarding Pointers

Chang and Lin have proposed an improved scheme [9] that uses forwarding pointers in virtual layer to reduce the update cost. The possible state of a user in this scheme is:

- When mobile user \( x \) enters the mobile communications network (i.e., user \( x \) turns the mobile on), a new record is created in both HLR and VLR in order to store the information of user \( x \). Thus, one HLR and one VLR accesses are necessitated.

- When VLR is active: mobile user \( x \) moves from one LA, \( i \) to LA, \( j \):
  - If the information of user \( x \) already exists in subVLR, \( k \), VLR, \( i \), must be deactivated and subVLR, \( k \), must be activated. Therefore, one VLR and one subVLR accesses should be performed.
  - If the information of user \( x \) cannot be found in subVLR, \( k \), a new record is created in subVLR, \( k \), and the information in previous subVLR must be deleted. Besides, VLR, \( i \), must be deactivated and subVLR, \( k \), must be activated. Therefore, one VLR and two subVLR accesses are required.

- When subVLR is active: mobile user \( x \) moves from virtual layer, \( i \) to virtual layer, \( j \):
  - If the information exists in VLR, \( k \), the information in VLR, \( k \), is updated. VLR, \( k \), must be activated and subVLR must be deactivated. Therefore, one VLR and one subVLR accesses are required. Furthermore, VLR, \( k \), must be activated.
and subVLR must be deactivated. Thus, one subVLR and two VLR accesses are required.

- When mobile user $x$ calls mobile user $y$:
  
  - If both user $x$ and user $y$ are in the same LA, the location of user $y$ is directly found from VLR, or by following the pointers chain. Thus, $l$ VLR accesses are needed.
  
  - If both user $x$ and user $y$ are not in the same LA, first the location of user $y$ is searched in VLR, and relevant pointers chain. Since the information cannot be found, the relevant VLR can be found from HLR. Finally, the location of user $y$ is directly found from VLR by following the pointers chain. Therefore, one HLR access and $2 \times l$ VLR accesses are required to find the location of user $y$.

- Finally, when user $x$ turns his/her mobile off, or exits from the mobile communications network, the information of user $x$ in HLR and VLR should be deleted. To do this, one HLR and $l$ VLR accesses are required.

2.5. Overlap Region

The Virtual Layer scheme [8] requires the reconstruction of the mobile communications network architecture. The architecture requires extra equipments. To overcome the reconstruction of the mobile communications network, the Virtual Overlap scheme [10] with time stamp has been proposed. Figure 2 depicts the structure of the Virtual Overlap Region in which the mobile user has registered last time. Therefore, in the Virtual Overlap scheme [10], each VLR has two fields: TS which indicates the time that a mobile user enters the associated LA, and OR which indicates the Overlap Region in which the mobile user has registered last time. Therefore,

- When mobile user $x$ enters the mobile communications network (i.e., user $x$ turns his/her mobile on), a new record is created in both HLR and VLR in order to store the information of user $x$. Thus, one HLR and one VLR accesses are necessary.

- When mobile user $x$ moves from LA$_i$ to LA$_j$:
  
  - If LA$_i$ and LA$_j$ are in the same virtual overlap region, a new record is created in VLR$_j$ and the TS field of VLR$_j$ records the current time. Therefore, one VLR access is necessitated.
  
  - If LA$_i$ and LA$_j$ are not in the same virtual overlap region, a new record is created in VLR$_j$ and the TS field of VLR$_j$ records the current time. Thus, a message is sent to HLR in order to update the user $x$ data. Furthermore, the information of user $x$ in previous OR (with seven VLRs) must be deleted. Therefore, one HLR and eight VLR accesses are required.

- When mobile user $x$ calls mobile user $y$:
  
  - If both user $x$ and user $y$ are in the same LA, the location of user $y$ is found from seven VLRs in the relevant OR. Thus, seven VLR accesses are needed.
  
  - If both user $x$ and user $y$ are not in the same LA, first the location of user $y$ is searched in VLR. Since the information cannot be found from VLR, a message is sent to HLR by VLR, and then the relevant VLR can be found in HLR. Finally, the associated overlap region is found from the OR field of VLR, and then the location of user $x$ is searched in seven VLRs in the relevant OR. Therefore, one HLR access and eight VLR accesses are required to find the location of user $y$.

- Finally, when user $x$ turns his/her mobile off or leaves the mobile communications network, the information of user $x$ in HLR and seven VLRs on the OR that user has resided before should be deleted. To delete the information of user $x$, one HLR and seven VLR accesses are necessary.

3. The Virtual Overlap Region with Forwarding Pointer Scheme

In this section, we shall propose a new approach for location updating based on the concepts of the virtual overlapping region and forwarding pointers. The goal of our VF is to
reduce the number of database accesses for updating and searching the information.

3.1. The Architecture of VF

Now, we detail the VF scheme. The VLR database that maintains current user location information keeps two fields as the LA ID and pointer PO. The LA ID field indicates the identification number of a LA and the PO field is a pointer to another VLR. Note that each LA has a unique identifier number. If the LA ID is –1, the PO field is used to find the LA ID in another VLR.

3.2. The Procedure of Location Registration

When a new mobile user (i.e., mobile user x) resides in a location area LAi, the associated database VLRi will create a new entry for mobile user x and will record the LA identification number. Then, the system gives the LA ID to the mobile user x and sends a message to the HLR to record the current location of mobile user x. When mobile user x moves, the procedure of the location registration is as follows:

- When mobile user x detects a new LAj, the mobile user x sends the LA ID that assigned previously in LAi to the associated service switch through its BS.
- Determine if the new LAj and previous LAi belong to the same overlap region.
- If yes, the VLRi will update its LA ID to LAj ID.
- If no, the VLRj will create a new entry for mobile user x and sends a message to VLRi in order to set a pointer to VLRj and change the LA ID field to –1. Then, a new location number is sent by VLRj to mobile user x.

3.3. The Procedure of Call Delivery

When mobile user x wants to call mobile user y in LAi, the following steps are required for the call delivery as:

- The system first searches mobile user y in VLRj.
- Determine whether mobile user y can be found in VLRj.
- If yes, the mobile user y’s LA is retrieved from the LA ID field:
  - According to the location information of VLR, the service switch MSCj can be found.
  - The service switch MSCj determines the cell location of the mobile user y and assigns a Temporary Location Directory Number (TLDN) to mobile user y. Then, the TLDN is returned from the MSCj to the MSCi. By this way, MSCi knows where to send the information relevant to mobile user x.
- If no, a message is sent to HLR:
  - From the HLR, the associated VLR can be found.
  - According to the location information of VLR, the service switch MSCj can be found.
  - The service switch MSCj determines the cell location of the mobile user y and assigns a TLDN. Then, the TLDN is returned from the current VLR to the HLR.
  - Upon receiving the TLDN, if the current VLR is different from the last VLR registered, the HLR updates the relevant pointer to point to the current VLR, and deletes the chain of forwarding pointers.
  - The HLR sends the TLDN to the original switch (i.e., MSCi) and the connection between the caller user and the called user is set up using the TLDN.

According to the above details, the numbers of database accesses in VF are as follows:

- When mobile user x enters a mobile communications network (i.e., user x turns his/her mobile on), a new record is created in both HLR and VLR in order to store the information of user x. Thus, one HLR and one VLR access are necessary.
- When mobile user x moves from LAi to LAj:
  - If LAi and LAj are in the same virtual overlap region, the LA ID field in VLRi is updated. Therefore, one VLR access is necessitated.
  - If LAi and LAj are not in the same virtual overlap region, a new record is created in VLRj and a pointer is set up from VLRi to VLRj, therefore, two VLR database accesses are needed.
- When mobile user x calls mobile user y:
  - If both user x and user y are in the same LAj, the location of user y is found from LA ID in the relevant VLR. Thus, one VLR access is needed.
  - If both user x and user y are not in the same LAj, first the location of user y is searched in VLRj. Since the information cannot be found from VLRj, a message is sent to HLR by VLRj and then the relevant VLR can be found in HLR. Finally, the location of user x is obtained from LA ID in the relevant VLR. Therefore, one HLR access and 2 VLR accesses are required to find the location of user y.
- Finally, when user x turns his/her mobile off or leaves the mobile communications network, the information of user x in HLR and / VLRs must be deleted. To delete the information of user x, one HLR and / VLR accesses are necessary.

4. Performance Evaluation

In this section, we shall compare VF scheme with the schemes stated in Section 2. First, the number of database accesses under different schemes will be illustrated for each possible action of a user. Then, we shall discuss the number of databases by an example.

4.1. Performance Evaluation of Database Accesses

In mobile communications, tracking mobile users could be the most important issue. Therefore, a good scheme must provide a small database when a user moves from one LA to another LA. Table 1 shows the comparison of different schemes in terms of the number of database accesses for possible status of a user. In this table, VF, Virtual Layer and Virtual Layer with Forwarding Pointers have small database accesses, but Virtual Layer and Virtual Layer with Forwarding Pointers need reconstruction of the mobile communications network. Furthermore, when the length of the chain in Forwarding Pointer and Virtual Layer with Forwarding Pointer schemes goes up, the number of database accesses increases. Since the access of HLR database takes more time, Overlap Region and VF reduces an update cost when an user goes back and forth in boundary of LAs (just need one VLR access) which is comparable with the two-tier architecture (that needs one HLR and two VLRs accesses). While searching the user location, the VF, two-tier architecture and Virtual Layer always provide small number of database accesses, and Overlap Region has more database accesses than other schemes.

Based on the number of database accesses, Table 2 ranks the proposed schemes when the Forwarding Pointer chain length is $l < 7$. When a user mobile is turned on, a new record is created in HLR and VLR databases. Therefore, the number of database accesses for all schemes are the same. When a user mobile is turned off, all information must be deleted. In this case, the overlap region scheme is the worst. For searching user information, again, the overlap region scheme has more database accesses. For a movement from one LA to another, which is more important in cellular networks, VF and Forwarding Pointer schemes are the best candidates and the two-tier scheme is the worst.

On the other hand, Table 3 depicts the ranking of schemes when the Forwarding Pointer chain length is $l \geq 7$. In this

situation, the number of database accesses for deleting and searching the information in VF, Forwarding Pointer and Virtual Layer with Forwarding Pointer goes up.

4.2. Impact of Users’ Mobility

Figure 3 shows an example in which user \( x \) moves from position A to position F through positions B, C, D, E, and F:

- Initially, user \( x \) enters LA\(_5\) or is turned on in LA\(_5\). The following procedures are performed:
  - VLR\(_5\) creates a new entry for user \( x \).
  - VLR\(_5\) sends a registration message to HLR to create an entry and to set a pointer to VLR\(_5\).

- When user \( x \) moves from A to B:
  - **Two-tier architecture.** VLR\(_9\) creates a new record for user \( x \) and sends a message to HLR to update information. Then, the information in VLR\(_5\) is deleted.
  - **Forwarding Pointer.** VLR\(_9\) creates a new record for user \( x \) and sends a message to VLR\(_5\) to set a pointer to VLR\(_9\).
  - **Virtual Layer.** When user \( x \) enters LA\(_9\), a new record is created in subVLR\(_2\) and VLR\(_5\) is deactivated. Then, user \( x \) enters the virtual layer 3 from virtual layer 2. Therefore, a new record is created in VLR\(_9\) and the information in VLR\(_5\) is deleted. Hence, a message is sent to HLR by VLR\(_9\) to update relevant information.
  - **Virtual Layer with Forwarding Pointer.** When user \( x \) enters LA\(_9\), a new record is created in subVLR\(_2\) and VLR\(_5\) is deactivated. Then, user \( x \) enters the virtual layer 3 from virtual layer 2. Therefore, a new record is created in VLR\(_9\) and the information in VLR\(_5\) is deleted. Hence, a message is sent to VLR\(_3\) to set a pointer to VLR\(_9\).
  - **Overlap Region with Time Stamp.** When a user enters LA\(_9\), because LA\(_9\) is in OR\(_5\) a new record is created in VLR\(_9\) and the TS field of VLR\(_9\) stores the time that user has entered LA\(_9\). Moreover, the OR field of VLR\(_9\) stores the user \( x \) overlap region number (OR\(_5\)).
  - **VF.** When a user enters LA\(_9\), the LA ID field in VLR\(_5\) is updated from 5 to 9 since LA\(_9\) is in OR\(_5\).

- Movement from position B to position C:
  - **Two-tier architecture.** VLR\(_{10}\) creates a new record for user \( x \) and sends a message to HLR to update information. Then, the information in VLR\(_9\) is deleted.
  - **Forwarding Pointer.** VLR\(_{10}\) creates a new record for user \( x \) and sends a message to VLR\(_9\) to set a pointer to VLR\(_{10}\).
  - **Virtual Layer and Virtual Layer with Forwarding Pointer.** When user \( x \) enters LA\(_{10}\), a new record is created in subVLR\(_2\) and VLR\(_9\) is deactivated. Furthermore, the information of user \( x \) is deleted from subVLR\(_2\).
- **Overlap Region with Time Stamp.** When a user enters LA_{10}, because LA_{10} is in OR_{5} a new record is created in VLR_{10} and the TS field of VRL_{10} records the time that user has entered LA_{10}. In addition, the OR field of VLR_{10} stores the user x overlap region number (OR_{5}).

- **VF.** When a user enters LA_{10}, the LA ID field in VLR_{5} is updated from 9 to 10 because LA_{10} is in OR_{5}.

- **Two-tier architecture.** VLR_{5} creates a new record for user x and sends a message to HLR to update information. Then, the information in VLR_{10} is deleted.

- **Forwarding Pointer.** VLR_{5} updates user x information, because the information already exists in VLR_{5}. Then, a message is sent to VLR_{10} to set a pointer to VLR_{5}.

- **Virtual Layer.** When user x crosses the boundary of virtual layers in the direction of C to D, VLR_{10} creates a new record and sends a message to HLR to update information. Then, the information in VLR_{9} is deleted. When a user reenters LA_{5} again, a new record is created in subVLR_{4} and VLR_{10} is deactivated. Furthermore, the information of user x is deleted from subVLR_{5}.

- **Virtual Layer with Forwarding Pointer.** When user x crosses the boundary of virtual layers in the direction of C to D, VLR_{10} creates a new record and sends a message to VLR_{9} to set a pointer to VLR_{10}. Then, when a user enters LA_{5}, a new record is created in subVLR_{4} and VLR_{10} is deactivated. Furthermore, the information of user x is deleted from subVLR_{5}.

- **Overlap Region with Time Stamp.** When a user enters LA_{5}, because LA_{5} is in OR_{5} a new record is created in VLR_{5} and the TS field of VLR_{5} stores the time that user has entered LA_{5}. Furthermore, the OR field of VLR_{5} stores the user x overlap region number (OR_{5}).

- **VF.** When a user enters LA_{5}, because LA_{5} is in OR_{5} the LA ID field in VLR_{5} is updated from 5 to 6.

- Finally, user x moves from position E to position F:

- **Two-tier architecture.** VLR_{11} creates a new record for user x and sends a message to HLR to update information. Then, the information in VLR_{6} is deleted.

- **Forwarding Pointer.** VLR_{11} creates a new record for user x and sends a message to VLR_{6} to set a pointer to VLR_{11}.

- **Virtual Layer.** When user x crosses the boundary of virtual layers in the direction of E to F, VLR_{6} creates a new record and sends a message to HLR to update information. Then, the information in VLR_{5} is deleted. Then, when user enters LA_{11}, a new record is created in subVLR_{7} and the information of user x is deleted from subVLR_{4}.

- **Virtual Layer with Forwarding Pointer.** When user x crosses the boundary of virtual layers in the direction of E to F, VLR_{6} creates a new record and sends a message to VLR_{5} to set a pointer to VLR_{6}. Then, when a user enters LA_{11}, a new record is created in subVLR_{7} and VLR_{6} is deactivated and subVLR_{7} is activated.

- **Overlap Region with Time Stamp.** When a user enters LA_{11}, because LA_{11} is not in OR_{5}, a new record is created in VLR_{11} and the TS field is set to the current time. In addition, the OR field of VLR_{11} is set to OR_{11}. Then, a message is sent to HLR by VLR_{11} to update the information. After all, the information of user x is deleted from all VLRs in OR_{5}.

- **VF.** When a user enters LA_{11}, because LA_{11} is not in OR_{5} a new record is created in VLR_{11} and a pointer is set up from VLR_{3} to VLR_{11}. In addition the LA ID field in VLR_{5} is updated to –1 and user x takes new LA ID from VLR_{11} (i.e., 11).

Let’s suppose that user y in LA_{14} wants to call user x. First, VLR_{14} is queried, but the relevant information cannot be found. Hence, a message is sent to HLR by VLR_{14}.

- **Two-tier architecture.** From the HLR database, the associated VLR (i.e., VLR_{11}) is found and the information is retrieved from VLR_{11}.

- **Forwarding Pointer.** From the HLR database, the associated VLR (i.e., VLR_5) is found and the information is retrieved from VLR_5 by following the chains (i.e., VLR_6, VLR_11).

- **Virtual Layer.** From the HLR database, the associated VLR (i.e., VLR_11) is found and the information is retrieved from VLR_11.

- **Virtual Layer with Forwarding Pointer.** From the HLR database, the associated VLR (i.e., VLR_5) is found and the information is retrieved from VLR_5 by following the chains (i.e., VLR_6, VLR_11).

- **Overlap Region with Time Stamp.** From the HLR database, the associated VLR (i.e., VLR_11) is found. Then, the information is searched in OR_11 that consists of VLR_6, VLR_7, VLR_10, VLR_11, VLR_12, VLR_15, and VLR_16.

- **VF.** From the HLR database, the associated VLR (i.e., VLR_5) is found and the information is retrieved from VLR_5 by following the chains (i.e., VLR_11).

Table 4 shows the number of database accesses among different schemes for this example. We assume that all database accesses have the same cost. Let the database access cost for HLR (\(C_{U,H}\)) be equal to

\[
C_{U,H} = \alpha \times C_{U,V}\tag{1}
\]

where \(C_{U,V}\) is the VLR access cost and \(\alpha \geq 1\). Then, the total database access cost (\(C_{U,T}\)) according to VLR access cost can be obtained from Eq. (2).

\[
C_{U,T} = C_{U,H} + C_{U,V}\tag{2}
\]

From Eq. (2), the normalized access cost value of \(C_{U,T}/C_{U,V}\) can be obtained (see the last row in Table 4). As a result for the example in Fig. 3, the VF has the smallest database accesses in total (11 accesses: 9 VLR and 2 HLR accesses). Therefore, this scheme is better than others. Virtual Layer and Virtual Layer with Forwarding Pointer need reconstruction of the mobile communications network. Overlap Region scheme reduces database access for updating, however, it needs more database accesses for searching the location of users.

According to Fig. 4, with the increase of \(\alpha\), the two-tier architecture scheme has larger cost than the other schemes. Note that the HLR database must be accessed for every action in mobile communications network including searching, updating, deleting, and creating new record. Since in VF, Forwarding Pointer and Virtual Layer with Forwarding Pointer, access to HLR is avoided by using the forwarding pointer chain from one VLR to another VLR, the cost of these schemes is lower than others.

5. Conclusion

In this paper, we have studied five location management schemes and the number of database accesses for inserting, updating, deleting, and searching operations. When a user frequently makes a call to other users, Overlap Region
needs more database accesses than others. In Forwarding Pointer, when a user frequently moves within boundaries of LAs, the number of database accesses becomes high. Virtual Layer and Virtual Layer with Forwarding Pointer need the reconstruction of mobile communications network. With the increases of the mobile users in the mobile communications network, the size of the HLR database goes up and the two-tier architecture cannot be a good scheme at all. This is because the HLR database must be accessed for every action including inserting, updating, deleting, and searching operations.

In addition, we have proposed a new scheme (VF) and compared it with other schemes. According to our comparisons, VF has a small number of database accesses when a user frequently moves within the boundary of LAs. For searching the user location, VF still has smaller database accesses than others. Therefore, VF could be the best candidate either when a user frequently moves within boundaries of LAs or frequently makes a call to other users.
